The Nonlinear Dispersion-Transfer Frontier

21 July 2026

Abstract

We compose the nonlinear geometry, normalized comparison, repair audit, retained-history interface, and topology results of Stages 41–49.

Theorem 1 (Strongest combined statement)**.** *On the certified local chart, nonlinear Fréchet dispersion admits an exact gauge-invariant event inclusion into the dependent Gaussian quadratic form. Under a normalized retained-state density comparison and chart-complement bound, the resulting continuous-channel row is at most*

$$7.757562504510382 \times 10^{-5},$$

inside its allocated budget. A complete positive-mass history table would therefore imply the certified adaptive cluster bound.

Proof. Stages 41–42 prove the geometric inclusion and normalized tail transfer. Stage 32 supplies the low row, and Stage 46 composes both rows with the chart complement before invoking Stage 36. □

The direct repair route does not supply the missing premise: lifting a single-star contraction to links has spill coefficient $1.635983\ldots$, whereas the upper-split sufficient threshold is $0.968323\ldots$.

Remark 1. *The boundary-uniform density and complement estimates remain unproved. Center barriers are not sector partition ratios; cut/orbit control and nonabelian integer topology also remain open. Hence no physical one-scale basin, RG trajectory, continuum theory, or mass gap follows.*
